Root Cause Determination

 $Qi \ Qi$

December 15, 2018

Introduction

An open challenge stated in the Quality Engineering Journal: there is a key quality characteristic that is measured once on a medical device component. The characteristic is crucial to ensure that the device will perform as intended. The value has to be sufficiently small to provide a real benefit to the patient.

We have extensive history on this characteristic with 1500 data points representing several years of a manufacturing process history. Close inspection of the data reveals that there are a few data points that fall outside of the specification, which is problematic. It appears that there is some skewness on the right side of the distribution, which may be the reason for the data points that fall outside of the specification. Although the frequency of points outside the specification is low, it is crucial to reduce this frequency in order to ensure a high level of quality.

A small experiment was done with 60 total samples, where 30 of them had the root cause and 30 did not. Experimental data shows significant difference in the mean response between these two groups.

Root cause is a possible factor leading to the skewness but this factor is not observed in the data set. So the purpose is to identify whether each subject belongs to root cause group or not, and estimate the frequency of root cause in the historical data set.

I assumed the population with a mixture of Gaussian distribution and use EM-algorithm to estimate the parameters. As long as I can obtain the estimator of proportion fractions, then the frequency of root cause is able to be estimated.

Distribution of Experimental Data

Test the normality of experimental data set:

```
test <- read.csv("Data for Root Cause Determination - Test Data.csv")
dat <- read.csv("Data for Root Cause Determination.csv")
shapiro.test(test[test$Group == "Test Group - Root Cause",]$Response)

##
## Shapiro-Wilk normality test
##
## data: test[test$Group == "Test Group - Root Cause",]$Response
## W = 0.9609, p-value = 0.3266

shapiro.test(test[test$Group == "Test Group - No Root Cause",]$Response)

##
## Shapiro-Wilk normality test
##
## data: test[test$Group == "Test Group - No Root Cause",]$Response
## W = 0.95875, p-value = 0.2877</pre>
```

From above result, we know for each group the data is normally distributed. Since sample size is 30 in each group, we do not have much power. Then I also tested goodness of fit of Gamma distribution:

```
gamma_test(test[test$Group == "Test Group - Root Cause",]$Response)

##

## Test of fit for the Gamma distribution

##

## data: test[test$Group == "Test Group - Root Cause",]$Response

## V = -1.2239, p-value = 0.3868

gamma_test(test[test$Group == "Test Group - No Root Cause",]$Response)

##

## Test of fit for the Gamma distribution

##

## data: test[test$Group == "Test Group - No Root Cause",]$Response

## V = -0.33574, p-value = 0.8123
```

Above results also show gamma distribution fits the data set.

Then I propose mixed normal distribution and mixed gamma distribution of original data set.

Mixture of Normal Distributions

Let z_i be the index of the Gaussian distribution from which x_i is sampled. The parameters to be estimated is $(\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \xi_1, \xi_2)$, where $\xi_1 + \xi_2 = 1$. Let $\theta_t = (\mu_{t1}, \mu_{t2}, \sigma_{t1}^2, \sigma_{t2}^2, \xi_{t1}, \xi_{t2})$

$$Q(\theta|\theta_t) = \sum_{z} p(z|x, \theta_t) \ln p(x, z|\theta) = \sum_{i=1}^{n} \sum_{k=1}^{2} p(z_i = k|x_i, \theta_t) \ln p(x_i, z_i = k|\theta)$$

Let $w_{ik} = p(z_i = k | x_i, \theta_t)$, then

$$\begin{split} w_{ik} &= \frac{p(z_i = k, x_i, |\theta_t)}{\sum_{k=1}^2 p(z_i = k, x_i | \theta_t)} = \frac{\xi_{tk} \phi(x_i | \mu_{tk}, \sigma_{tk}^2)}{\sum_{k=1}^2 \xi_{tk} \phi(x_i | \mu_{tk}, \sigma_{tk}^2)} \\ Q(\theta | \theta_t) &= \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \ln(\xi_k / \sqrt{2\pi}) - \frac{1}{2} \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \ln \sigma_k^2 - \frac{1}{2} \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \frac{(x_i - \mu_k)^2}{\sigma_k^2} \\ &\frac{\partial Q(\theta | \theta_t)}{\partial \mu_k} = 0 \Rightarrow \mu_k = \frac{\sum_{i=1}^n w_{ik} x_i}{\sum_{i=1}^n w_{ik}} \\ &\frac{\partial Q(\theta | \theta_t)}{\partial \sigma_k^2} = 0 \Rightarrow \sigma_k^2 = \frac{\sum_{i=1}^n w_{ik} (x_i - \mu_k)^2}{\sum_{i=1}^n w_{ik}} \\ &\xi_k = \frac{1}{n} \sum_{i=1}^n w_{ik} \end{split}$$

If the classification of some data points is known, then some w_{ik} are known. Suppose $z_1, ..., z_{n_1}$ are unknown, $z_{n_1+1}, ..., z_n$ are known, then $w_{1k}, ..., w_{n_1k}$ are estimated as above approach and $w_{(n_1+1)k}, ..., w_{nk}$ are equal to either 1 or 0 according to the value of $z_{n_1+1}, ..., z_n$.

Implement in R

R Functions Creation and Evaluation by Simulation Study

```

If we only use experimental data, then the estimated proportion parameters are 0.3 and 0.7, which is not close to the truth (0.5 and 0.5). If we use experimental data without classification information first and then use experimental data with classification information, the estimated proportion parameters are very close to the truth. Therefore, partial classification information can help to improve the accuracy of parameter estimation.

When I only use observed data, the estimated proportion parameters are 0.937 and 0.063. When I use pooled data, the estimated proportion parameters are 0.673 and 0.327, which means the estimated proportion parameters of observed data are 0.680 and 0.320.

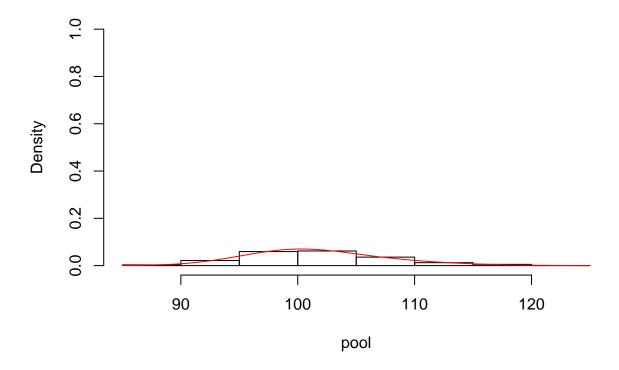

```
## overlay observed data and estimated parameters from observed data
f1 <- function(x){
  0.937 * dnorm(x, 100.711, 5.139) + 0.063 * dnorm(x, 113.659, 3.633)
}
hist(dat$Response, probability = TRUE, ylim = c(0, 1))
curve(f1, add = TRUE, col = "red")</pre>
```

Histogram of dat\$Response

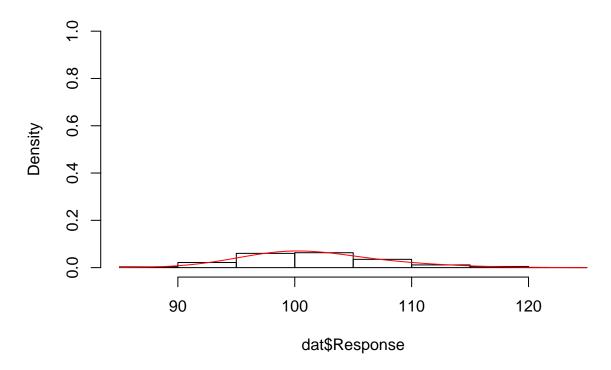

```
## overlay pooled data and estimated parameters from pooled data
f2 <- function(x){
    0.673 * dnorm(x, 99.464, 4.662) + 0.327 * dnorm(x, 106.178, 6.013)
}
pool <- double(nrow(dat) + nrow(test))
pool[1:nrow(dat)] <- dat$Response
pool[-(1:nrow(dat))] <- test$Response
hist(pool, probability = TRUE, ylim = c(0, 1))
curve(f2, add = TRUE, col = "red")</pre>
```

Histogram of pool

```
## overlay observed data and estimated parameters from pooled data

  0.68 * dnorm(x, 99.464, 4.662) + 0.32 * dnorm(x, 106.178, 6.013)
}
hist(dat$Response, probability = TRUE, ylim = c(0, 1))
curve(f3, add = TRUE, col = "red")</pre>
```

Histogram of dat\$Response

Mixture of Gamma Distributions

Let z_i be the index of the Gaussian distribution from which x_i is sampled. The parameters to be estimated is $(\alpha_1, \alpha_2, \beta_1, \beta_2, \xi_1, \xi_2)$, where $\xi_1 + \xi_2 = 1$. Let $\theta_t = (\alpha_{t1}, \alpha_{t2}, \beta_{t1}, \beta_{t2}, \xi_{t1}, \xi_{t2})$

$$Q(\theta|\theta_t) = \sum_{z} p(z|x, \theta_t) \ln p(x, z|\theta) = \sum_{i=1}^{n} \sum_{k=1}^{2} p(z_i = k|x_i, \theta_t) \ln p(x_i, z_i = k|\theta)$$

Let $w_{ik} = p(z_i = k | x_i, \theta_t)$, then

$$\begin{split} w_{ik} &= \frac{p(z_i = k, x_i, |\theta_t)}{\sum_{k=1}^2 p(z_i = k, x_i | \theta_t)} = \frac{\xi_{tk} \Gamma(x_i | \alpha_{tk}, \beta_{tk})}{\sum_{k=1}^2 \xi_{tk} \Gamma(x_i | \alpha_{tk}, \beta_{tk})} \\ Q(\theta | \theta_t) &= \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \ln \xi_k - \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \ln \Gamma(\alpha_k) - \sum_{k=1}^2 \sum_{i=1}^n w_{ik} \alpha_k \ln \beta_k + \sum_{k=1}^2 \sum_{i=1}^n w_{ik} (\alpha_k - 1) \ln x_i - \sum_{k=1}^2 \sum_{i=1}^n \frac{w_{ik} x_i}{\beta_k} \\ \xi_k &= \frac{1}{n} \sum_{i=1}^n w_{ik} \\ \frac{\partial Q(\theta | \theta_t)}{\partial \alpha_k} &= 0 \Rightarrow \frac{\Gamma(\alpha_k)'}{\Gamma(\alpha_k)} = \frac{\sum_{i=1}^n w_{ik} \ln x_i - \sum_{i=1}^n w_{ik} \ln \beta_k}{\sum_{i=1}^n w_{ik}} \\ \frac{\partial Q(\theta | \theta_t)}{\partial \beta_k} &= 0 \Rightarrow \beta_k = \frac{\sum_{i=1}^n w_{ik} x_i}{\alpha_k \sum_{i=1}^n w_{ik}} \end{split}$$

$$\Rightarrow \frac{\Gamma(\alpha_k)'}{\Gamma(\alpha_k)} = \frac{\sum_{i=1}^n w_{ik} \ln x_i - \sum_{i=1}^n w_{ik} \ln \frac{\sum_{i=1}^n w_{ik} x_i}{\alpha_k \sum_{i=1}^n w_{ik}}}{\sum_{i=1}^n w_{ik}}$$
 Let $\Psi(\alpha_k) = \frac{\Gamma(\alpha_k)'}{\Gamma(\alpha_k)}$,
$$f(\alpha_k) = \Psi(\alpha_k) - \frac{b - a \ln \frac{c}{a\alpha_k}}{a}$$
 where $a = \sum_{i=1}^n w_{ik}$, $b = \sum_{i=1}^n w_{ik} \ln x_i$, $c = \sum_{i=1}^n w_{ik} x_i$.
$$f'(\alpha_k) = \Psi'(\alpha_k) - \frac{1}{x}$$

If the classification of some data points is known, then some w_{ik} are known. Suppose $z_1, ..., z_{n_1}$ are unknown, $z_{n_1+1}, ..., z_n$ are known, then $w_{1k}, ..., w_{n_1k}$ are estimated as above approach and $w_{(n_1+1)k}, ..., w_{nk}$ are equal to either 1 or 0 according to the value of $z_{n_1+1}, ..., z_n$.
